

# The Command Center Field Guide

How the system is put together, the exact rules that decide where a patient appears, and how to trace a problem back to whoever can fix it.

## 01 What this document is

This guide states **only rules that are actually defined in the system** — a named column, a named role, a specific comparison the code performs. Every rule block cites the file it comes from so you can have someone check it.

Where a behaviour is a judgement call rather than a defined rule, this guide says so explicitly instead of guessing. Where a number appears (30 seconds, 8 attempts, 95 seconds), it is read from the code, not estimated.

### What it does not cover

---

- **How to do your job in each stage.** This is about the machinery, not the clinical or insurance work.
- **Monday automations individually.** They are configured on the boards, not in code, so they can't be read the same way. This guide tells you when to suspect one.
- **The Railway services' internals.** They own certain columns; this guide names which, and stops there.
- **Auth Denied.** That stage is under construction and deliberately has no manager views built for it.

#### A NOTE ON THE ENGINEERING DOCS

The repository's `CLAUDE.md` is the engineering reference, and it is far more detailed than this. It can also fall behind the code: while preparing this guide, its description of the Patient Intake split was found to describe a rule that was **changed on 10 August 2026**. Where this guide and `CLAUDE.md` disagree, the rules stated here were read from the code on the date on the cover.

## 02 What the Command Center is

One paragraph that the rest of the document depends on.

The Command Center is a **web app that reads and writes Monday.com columns**. It has no patient database of its own — every patient fact you see on screen is a column on a Monday board, fetched moments ago. (It does keep two small things of its own: a cache of the role-bar numbers in your browser, and the list of who can see what, stored in a file in GitHub.)

Patients move between stages through **Monday's own automations**. Each board has a status column acting as the **Stage Advancer**; automations configured on the board watch it and move the item. The app writes the stage data first, confirms it landed, and writes the Stage Advancer last.

FIGURE 1

**Four different things write to the same columns** — the app, the board's automations, the Railway bots, and anyone editing the board by hand. The app only ever reads them back, on a timer. That is why “the board is right but my screen is wrong” and “my screen looked right but the board is blank” are unrelated problems with different owners.

### The refresh delay is real, and it is two different numbers

The patient *lists* on a role page refresh every **30 seconds**. The *numbers* on the role bars refresh every **60 seconds**. Neither is instant, and they are not in step with each other.

So a list and its own count can legitimately disagree for up to a minute after something changes. Before reporting a mismatch, reload and look again.

Defined in `src/hooks/masheke/useMondayPatients.ts`, `src/hooks/samantha/useMondayPatients.ts` (`POLL_MS = 30_000`) and `src/hooks/useRoleCounts.ts` (`POLL_MS = 60_000`).

FIGURE 2

The six boards a patient passes through, and the roles that work each one.  
Movement between boards is performed by Monday automations, not by the app.

## The five owners

Every problem in this system belongs to one of five categories. Naming the category is most of the diagnosis, because it decides who can fix it.

### ● BOARD DATA

A value in a column is wrong, missing, or was never set. Fixed **on the board** by anyone with access.

### ● BOARD SETUP

A column, a status label, or an automation was renamed, deleted, or switched off. Fixed **in Monday by a board admin**. No code.

### ● A BOT

A Railway service owns those columns — eligibility, DVS, doctor lookup, texting. **Backend work**; the app cannot fix it.

### ● THE SAVE

The app attempted a write and it did not land, or has not landed yet. **Check what the toast said**, then retry or escalate.

### ● APP RULES

Which queue a patient lands in, whether they're counted, which chart shows them. **Code change** — and see section 07.

### THE FORK EVERY DIAGNOSIS STARTS AT

**Open the patient's item on the Monday board and read the columns themselves.**

If the board is wrong, something wrote the wrong value or nothing wrote at all — that is Board data, Board setup, A bot, or The save. If the board is right and the screen disagrees, the data is fine and a rule is filtering or counting it — that is App rules. One look splits the problem in half.

## 04 How a patient reaches a queue

A patient must pass three gates in order to appear in somebody's work list. Nearly every "where did they go?" question is one of these three.

FIGURE 3

The three gates, in the order the code applies them. The top-right outcome is the dangerous one: a patient who matches no role is counted nowhere and listed nowhere, and nothing anywhere reports it.

## GATE 1 Which queue — board, group, and for some stages a splitter column

Most stages are simply “this board, this group”. Three places split one group into more than one role:

- **Medical Evaluation** is one group split by the *Stage Advancer* text, matched exactly: `Evaluate MN`, `Send Request`, `Confirm Receipt`, `Chase Clinicals`, `Doctor Appointment`.
- **Chase Clinicals** splits again on *Clinicals Method*: `Parachute` or `Email` go to **Chase — Email & Parachute**; everything else, including blank, goes to **Chase — Fax**.
- **Profile Send Off** separates *Already In System* = `Yes` into its own role. Everything else in the `1. Intake` group is Verified Referrals.

CORRECTED — CHANGED 10 AUGUST 2026

**Patient Intake is no longer a split of the `1. Intake` group.** It is now the DTC form's own two groups on the same board, and nothing else. Referral Type and Referral Source no longer route anyone to it — they are still shown and still labelled in Oversight, but they no longer decide the queue.

If you have been told that a “Patient” referral type moves someone to Patient Intake, that is out of date.

Defined in `src/lib/profile/referralSplit.ts` and duplicated in `src/hooks/useRoleCounts.ts`.

## GATE 2 Due today — and there are three different rules

This is the most common source of confusion, because the rule is not the same on every board. There are three distinct shapes:

| STAGE                                                                  | CONTROLLING COLUMN                                  | HIDDEN FROM THE QUEUE WHEN...                                                                                                                 |
|------------------------------------------------------------------------|-----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| Evaluate, Send Request, Confirm Receipt, Chase x2, Doctor Appointments | Next Action Date                                    | The date is <b>in the future</b> . Blank, today, or past all count as due.                                                                    |
| Benefits, Submit Auth                                                  | Follow Up <i>status</i> and Follow Up Date together | Status is <code>Follow Up</code> <b>and</b> the date is blank or in the future. A <code>Follow Up</code> whose date has arrived is due again. |
| Auth Outstanding, DVS                                                  | Follow Up Date only                                 | The date is in the future. The status column is <b>ignored entirely</b> , and a <b>blank date counts as due</b> .                             |
| Welcome Call                                                           | Follow Up status                                    | Status is <code>Done</code> .                                                                                                                 |
| Final Confirmation                                                     | — none —                                            | Never. This group has <b>no follow-up rule at all</b> ; only escalation removes a patient.                                                    |
| Verified Referrals, Already In System, Patient Intake                  | Follow Up status                                    | Status is <code>Done</code> .                                                                                                                 |
| Scheduled Calls                                                        | Booked time of day                                  | The booked time has passed, or the booking is <code>Canceled</code> . Booked today with no time on file still counts.                         |
| Subscription, Update Clinicals                                         | — none —                                            | Never. These count every item in the group.                                                                                                   |

So “why is this still showing?” and “why did this vanish?” have different answers depending on which stage you are standing in. Check which column actually controls that stage before concluding anything.

Defined in `src/hooks/useRoleCounts.ts`; the role pages mirror it via each role's `useMondayPatients` hook.

### GATE 3 Escalation removes the patient from the rep — with one exception

An escalated patient leaves the rep's list *and* the rep's count, and appears in a manager column in Pipeline Oversight. That is what escalating is for. There are two rungs:

- **Manager Escalation Required** — the *Manager Intervention* column.
- **Final Escalation Required** — the *Final Decisions* column. On the Medical Evaluation board this specifically means a rep has **proposed** that the patient be marked stuck; a manager approves or returns it. It is a proposal, not a decision.

**On the Medical Evaluation board, a proposed-stuck patient is counted in neither the active count nor the escalated count.** They are skipped entirely, and are reached through the manager views.

#### THE EXCEPTION

**DVS ignores escalation.** Escalated patients stay in the DVS queue and the DVS count, because the DVS queue keys off the DVS and claims status columns instead. An escalation label carried in from an earlier stage must not hide them.

Defined in `src/hooks/useRoleCounts.ts`. Escalation columns: Medical Evaluation `color_mm1x7997`, Insurance `color_mm2vsh2f`, Welcome Call `color_mm1x7997`.

FIGURE 4

Escalation is a ladder, not a switch. A rep can only push a patient up; only a manager sends one back down. Sending a patient back clears the escalation, which is what returns them to the rep's list.

#### THE FAILURE MODE THIS SYSTEM IS PRONE TO

**A patient can end up in no queue at all, and nothing will report it.** If a patient reaches a state that no rule accounts for — a Stage Advancer value nobody wrote a branch for, say — every filter skips them. No error, no warning, no red count.

This is why “nothing looks wrong” is not evidence that nothing is wrong, and why a patient who *feels* stuck is worth reporting even when you cannot point at anything specific.

## 05 What happens when you save

The main “Send to Monday” actions run a four-phase transaction. Knowing its shape tells you what a failure means.

Monday's API confirms a write *before* the value is searchable. If the app flipped the Stage Advancer immediately, the automation could fire and read the **old** values of the other columns — sending stale data to the next stage. The four phases exist to prevent exactly that.

FIGURE 5

The abort on the right is the safety net working, not a bug. It means the app could not prove the data had landed, so it refused to trigger the automation — which would have carried stale values to the next stage.

### The three toasts, and exactly what each one means

The message you get after a save is the single most useful piece of diagnostic information in the app. There are three, and they are not interchangeable:

| WHAT YOU SAW                | WHAT IT MEANS                                                                         | WHAT TO DO              |
|-----------------------------|---------------------------------------------------------------------------------------|-------------------------|
| "... — confirmed in Monday" | Everything wrote and was read back successfully. The Stage Advancer was written last. | Nothing. It is durable. |

| WHAT YOU SAW                                                | WHAT IT MEANS                                                                                                    | WHAT TO DO                                                                                  |
|-------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>“Data in server — Monday confirmation still pending”</b> | The gateway has durably accepted the job and <b>it will run</b> . The app stopped waiting for Monday to confirm. | <b>Do not repeat the save.</b> Repeating it writes twice. Check the board in a few minutes. |
| <b>“Save failed — nothing was written”</b>                  | The transaction aborted. The Stage Advancer was <b>not</b> written, so the patient did not advance.              | Retry. If it fails again, report it — the item link and the time are what's needed.         |

Defined in `src/lib/shared/verifiedWrite.ts`. The pending case is `GatewayPendingError`; the panels that surface it are Chase Clinicals, Confirm Receipt, and the Doctor Appointments panel and dialog.

WORTH KNOWING

Not every action in the app runs this four-phase transaction. The six main “Send to Monday” flows do. Some smaller inline actions — logging an attempt, marking complete, the escalation dialog, the Subscription save — write more directly and have less verification behind them. That difference is documented for engineers in the repository's write-reliability audit; operationally, it means **a save that showed no toast at all is worth checking on the board**.

## 06 Triage — symptom to owner

Find the symptom, do the one check, read the chip.

FIGURE 6

Two looks — the columns, then the Activity Log — narrow any problem to one of the five owners. The Activity Log is built into Monday and shows who changed which column, to what, and when.

### FAMILY A — "WHERE IS MY PATIENT?"

#### A patient disappeared from a rep's queue

● BOARD DATA

##### CHECK

The **Escalation** column, then the controlling column for that stage (Gate 2 table).

##### IF ESCALATED

They are in a manager column. This is the designed behaviour, not a fault.

##### IF SNOOZED

They return on the follow-up date. Note that Auth Outstanding and DVS ignore the status column entirely.

## A patient is in no queue and in no count

● APP RULES

### CHECK

The **Stage Advancer** value. Is it one of the five exact strings listed under Gate 1?

### MEANING

A value with no matching branch is skipped by every filter. Nothing reports it.

### FIX

Either the value is wrong on the board (Board data), or the app is missing a branch (App rules). Report with the item link.

## A patient is on the right board but in the wrong queue

● BOARD DATA

### CHECK

The splitter for that stage — *Clinicals Method* for Chase, *Already In System* for Profile Send Off.

### NOTE

A **blank** Clinicals Method routes to Chase — Fax by design, so that nobody falls through.

### FIX

Set the column on the board; the patient moves queues within a minute.

## An escalated patient is not in any manager column

● APP RULES

### CHECK

Which escalation label the item carries, and which stage it is in.

### WHY IT MATTERS

Escalation removes a patient from the rep's list. If no manager chart also matches them, they are invisible everywhere.

### FIX

Report it. This is the highest-priority class of bug in the system.

### A rep says they saved it; the board is blank

● THE SAVE

CHECK

Ask what the toast said (section 05), then read the item's **Activity Log**.

NO WRITE LOGGED

It never reached Monday. Redo it and watch the toast.

WRITTEN, THEN CHANGED

An automation or a bot overwrote it — that is Board setup or A bot, not the app.

### It saved, but the patient never advanced

● BOARD SETUP

CHECK

Whether the **Stage Advancer** actually changed on the item.

IT DIDN'T CHANGE

The save aborted at Phase 2 on purpose — see Figure 5. Retry.

IT CHANGED, NOTHING MOVED

The Monday automation is off, deleted, or erroring. A board admin checks it.

### “Data in server — Monday confirmation still pending”

● THE SAVE

MEANING

The job is durably queued on the server and **will** run. It is not lost.

DO

Wait, then check the board.

DO NOT

**Do not redo the save.** Repeating it writes twice.

## One column reads blank for every patient

● BOARD SETUP

### CHECK

Whether that column was recently deleted and re-added on the board.

### MEANING

Columns are matched by a hidden ID, not by their title. Deleting and recreating a column gives it a new ID; the app keeps asking for the old one and gets nothing, with no error.

### RULE

**Rename columns freely. Never delete and recreate one.** A rename is safe; a recreate silently breaks reads.

## A status label has a near-duplicate on the board

● BOARD SETUP

### CHECK

The label list for that column — look for two entries differing only in spacing or capitalization.

### MEANING

Some writes match labels by exact text. If the text no longer matches, Monday creates a new label rather than failing.

### RULE

Flag any status-label rename *before* it happens. Several rules compare exact strings such as Chase Clinicals and Parachute.

## FAMILY C — “THE NUMBERS DON'T AGREE”

## A list and its own count disagree

● THE SAVE

### CHECK

Reload and wait a minute. Lists refresh every 30 seconds, counts every 60.

### MEANING

A gap of up to a minute after any change is expected and not a fault.

### IF IT PERSISTS

Then it is worth reporting as App rules.

## A role bar and an Oversight chart disagree

● APP RULES

### CHECK

Whether the patients in the gap are escalated, and by how many the two differ.

### MEANING

The same rule is written in several places and one copy has drifted. See section 07.

### REPORT

Give every number you can see — bar, list, and chart. The pattern of disagreement identifies which copy drifted.

## The burndown shows a role as “not connected”

● APP RULES

### CHECK

Whether it is a recently added role.

### MEANING

The start-of-day snapshot has no entry for that role, so it shows “not connected” rather than a misleading zero. That is deliberate.

### FIX

Code, in both snapshot generators.

## Start-of-day numbers look wrong all day

● APP RULES

### CHECK

Whether the live counts look right. If only the comparison is off, it is the snapshot.

### MEANING

The snapshot is taken once each weekday morning. If its rules drift from the live ones you get phantom in/out movement all day.

### FIX

Code. It corrects itself the next morning once the underlying rule is fixed.

## The FAX bar says “Done!” but faxes are in the inbox

● BOARD DATA

### MEANING

Once the unread count first reaches zero on a given day, the bar stays “Done!” until midnight Eastern, even as new faxes arrive.

### FIX

Nothing — this is the defined behaviour. Work the Fax Inbox page directly rather than the bar.

## Eligibility results stay blank

● A BOT

### CHECK

That Name, DOB, insurance and Member ID were filled in **before** the check ran. If they weren't, the run is aborted on purpose and the check never fires.

### TIMING

Results are polled every 4 seconds and revealed once they have been stable for 10 seconds. The whole run times out at 95 seconds.

### MEANING

The app never writes eligibility results — a separate service does. A permanently blank field means that service did not write it.

### FIX

Backend. Corrections are made through Profile Send Off; the Insurance board cannot run an eligibility check at all.

## DVS or claims are not progressing

● A BOT

### CHECK

The DVS and claims status columns on the item.

### MEANING

DVS is automatic — that page is a read-only monitor. A failed or manual-review result escalates the patient by board automation.

### NOTE

Supplies and pump claims are **separate columns**. A pump problem will not show in the supplies column.

## A fax or email did not send

● A BOT

### CHECK

The recipient address or fax number on the item, and that the person is signed in.

### MEANING

Sending runs through a separate mail service and RingCentral, and does not touch Monday.

### NOTE

Email recipients receive **one grouped message**; each fax number receives its own separate message.

## Incoming calls stopped appearing on screen

● A BOT

### CHECK

That person's own ring setting: `all`, `list`, or `off`.

### IMPORTANT

A narrowed setting silences **that person's screen only**. It can never make a call unanswerable by someone else.

### IF IT'S EVERYONE

The call feed itself is down. There is a health check for exactly this — ask Josh.

## Blank screen, or a page will not load

● THE SAVE

### DO

Reload the tab once.

### MEANING

A tab left open across a new release loses the files it was going to load next. The app reloads itself once automatically when it detects this; a manual refresh does the same.

### IF A RELOAD DOESN'T FIX IT

Then report it.

## 07 Why a fix sometimes half-works

This explains a specific, recurring pattern of confusion, and it is worth knowing even if you never open the code.

A queue rule is not written once. The same rule is repeated in **five separate places**, because five parts of the system answer five different questions — and three of them cannot share code with the others.

FIGURE 7

Change four of the five and nothing errors. You get a list that is right and a count that is wrong, or a chart showing a patient the list does not. That mismatch is a signature: when a number and a list disagree and the refresh delay has already passed, this is the mechanism to suspect.

What this means for you in practice: when reporting a counting problem, **name every place you saw it**. "The bar says 12, the list shows 9, and the Oversight chart says 14" identifies which copy drifted. "The count is wrong" does not.

The rule files themselves carry this warning. See the header comments in `src/lib/profile/referralSplit.ts` and `src/hooks/useRoleCounts.ts`.

## 08 Where to look, and how to report

Four places, in the order you should reach for them.

| TOOL                                                          | ANSWERS                                                                                                                                                                             | WHO                        |
|---------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------|
| <b>The item's Activity Log</b><br>built into Monday           | Who changed which column, to what, and exactly when. The most useful diagnostic in the whole system, and it requires no special access.                                             | Anyone with board access   |
| <b>Pipeline Oversight</b><br>System Management<br>→ Oversight | Where escalated patients went, and which manager column holds them. Every escalated patient is meant to land in one of these columns; one that lands in none is invisible app-wide. | Managers                   |
| <b>The gateway audit log</b>                                  | Every request the app made — so you can establish whether a save was even attempted. Records metadata only; no patient data is stored there.                                        | Josh — it is key-protected |
| <b>The health checks</b>                                      | Whether the plumbing is alive. The gateway, the texting service and the incoming-call feed each have one.                                                                           | Josh                       |

### Reporting so it can be fixed the same day

The fastest reports answer the fork in section 03 before anyone has to ask:

```
Patient:      [name + link to the Monday item]
Stage/queue:  [which page, chart or role bar]
Expected:     [what you thought would happen]
Saw:         [what actually happened]
Toast:        [exact wording, if there was one]
When:         [date + roughly what time]
On the board: [what the relevant columns say right now]
Also seen in: [any other count, list or chart that disagrees]
```

The last three lines save the most time. **Toast** distinguishes the three save outcomes in section 05. **On the board** settles whether it is a data problem or an app problem.

**Also seen in** points straight at the section 07 mismatch.

## 09 Reference

Every role defined in the system, and the words you will hear.

### Roles, boards and routes

| ROLE AS SHOWN                       | BOARD              | PAGE                                  | NOTES                                                        |

## Words you will hear

|                                               |                                                                                                                                                                                          |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Stage Advancer</b>                         | The one status column per board that Monday's automations watch. Changing it is what moves a patient to the next stage. The app writes it last, after confirming everything else landed. |
| <b>Next Action Date</b>                       | Controls the queue on the Medical Evaluation board. Blank, today or past all mean due now; only a future date hides the patient.                                                         |
| <b>Follow Up / Follow Up Date</b>             | The snooze mechanism on the other boards. Which of the two actually controls the queue depends on the stage — see the Gate 2 table.                                                      |
| <b>Escalation</b>                             | Removes a patient from the rep's list and count, and puts them in a manager column. DVS is the exception and ignores it.                                                                 |
| <b>Propose Stuck</b>                          | A rep's request that a patient leave the pipeline. It is a proposal only; a manager approves or returns it. It appears as "Final Escalation Required".                                   |
| <b>Manager Intervention / Final Decisions</b> | The two manager columns in Pipeline Oversight, corresponding to the two escalation labels.                                                                                               |
| <b>Verified write</b>                         | The four-phase save in section 05: snapshot, write, read back to confirm, then flip the Stage Advancer. If it cannot confirm, it aborts rather than advancing.                           |
| <b>Gateway</b>                                | The server the app talks to Monday through. It holds the credentials and logs every request, which is what makes an audit possible.                                                      |
| <b>Baseline</b>                               | The start-of-day count snapshot the burndown compares against, taken each weekday morning.                                                                                               |
| <b>Stedi</b>                                  | The insurance eligibility check. A separate service runs it and writes the results to Monday; the app requests it and waits.                                                             |

|                           |                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>DVS</b>                | The automatic Medicaid verification stage. Bot-run; the page is a read-only monitor.                                              |
| <b>Parachute</b>          | An outside source for clinical documents. In the app, Email and Parachute share one queue.                                        |
| <b>Masheke / Samantha</b> | Long-standing internal nicknames for the Medical Evaluation board and the Insurance board respectively. Same boards, older names. |

Prepared for Medically Modern operations. Every rule in this document was read from the source on 11 August 2026 at commit `b5a5f8f`. Rules change — when something here stops matching what you see, that is worth reporting too.
